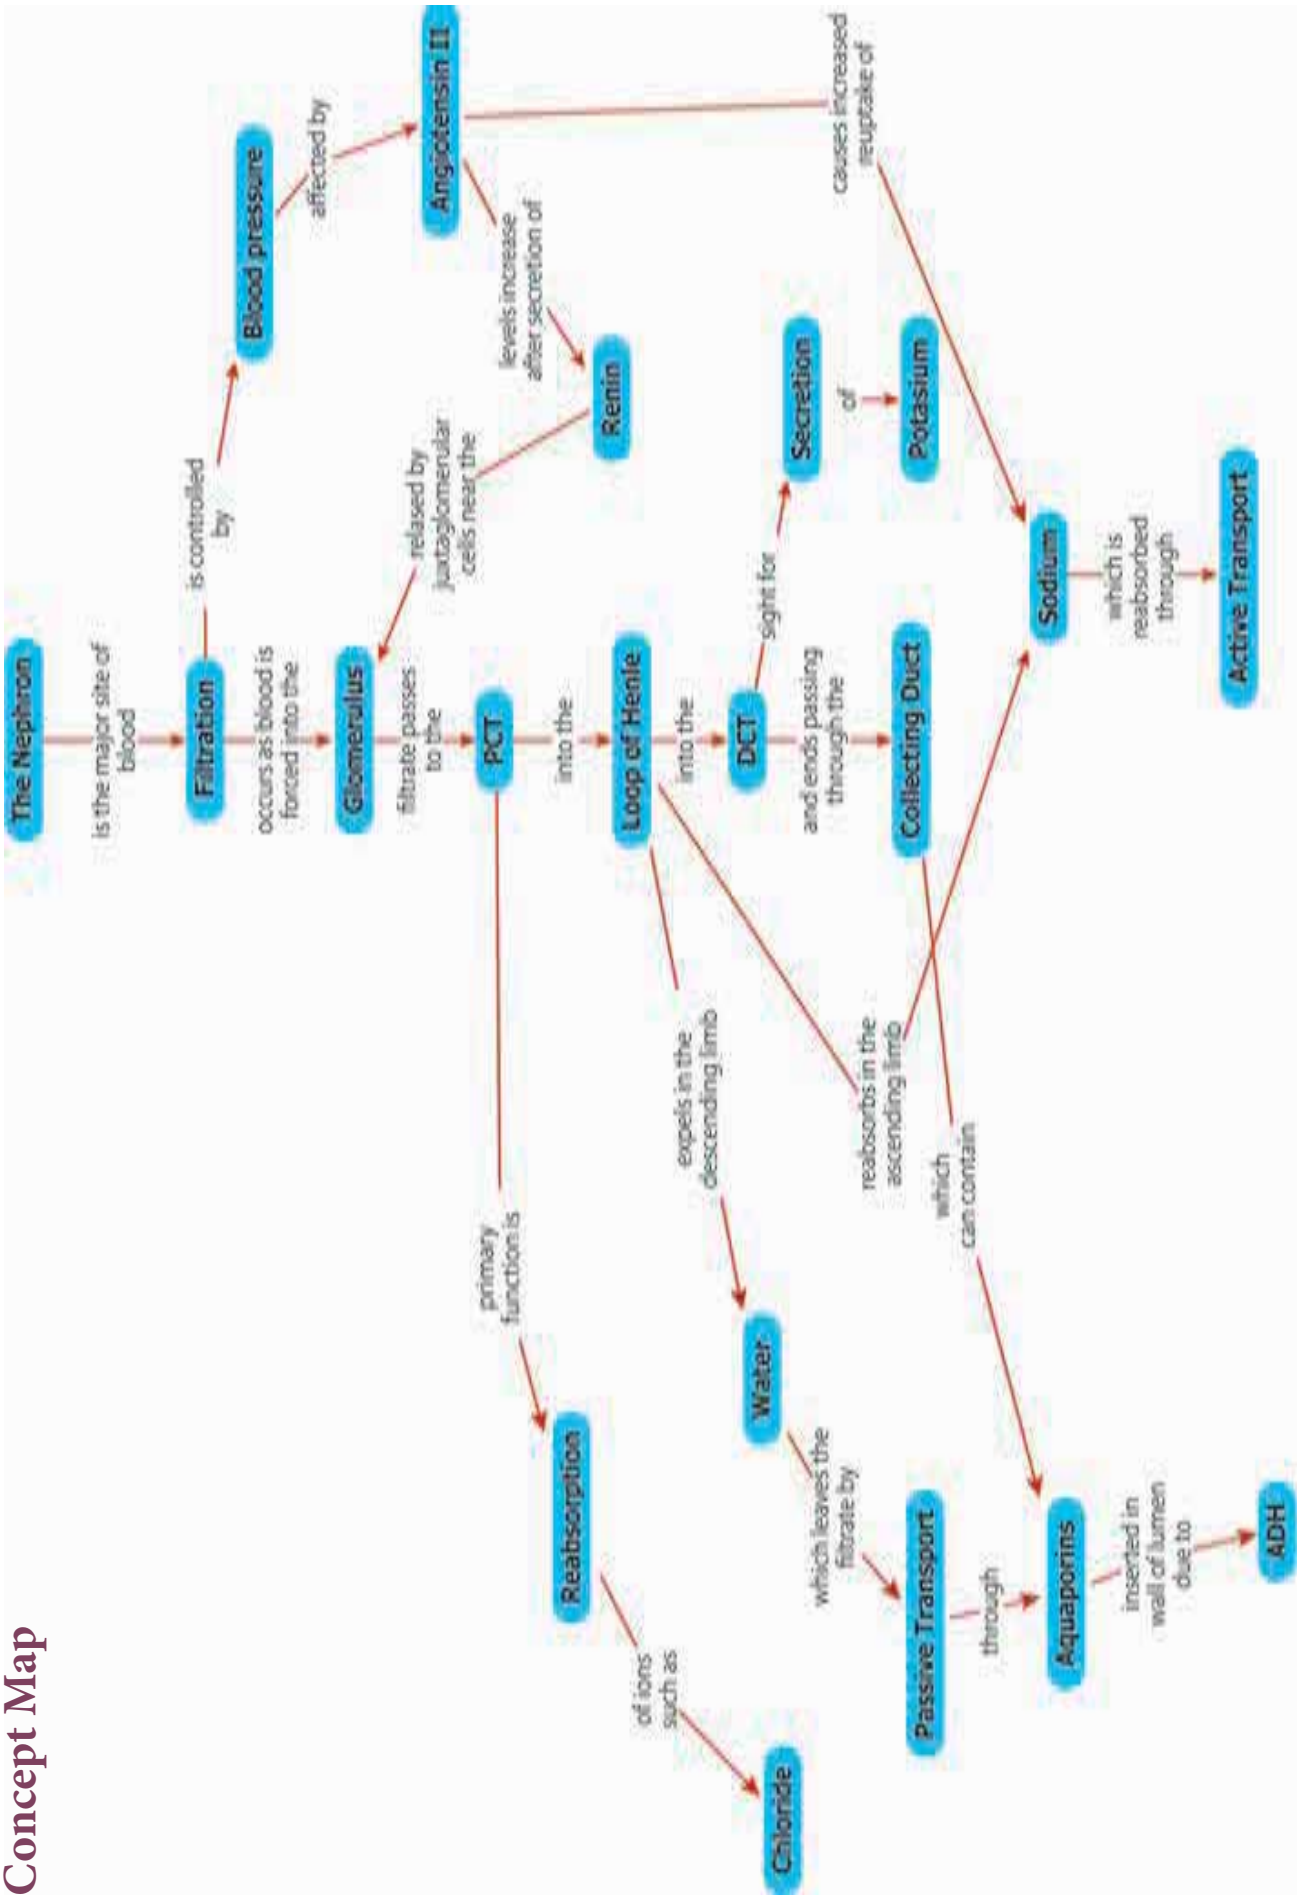
Concept Map



The Nephron
is the major site of blood
Filtration
is controlled by
Blood pressure
affected by
Angiotensin II
causes increased reuptake of
Sodium
which is reabsorbed through
Active Transport
occurs as blood is forced into the
Glomerulus
released by juxtaglomerular cells near the
Renin
levels increase after secretion of
filtrate passes to the
PCT
into the
Loop of Henle
into the
DCT
sight for
Secretion
of
Potasium
and ends passing through the
Collecting Duct
primary function is
Reabsorption
of ions such as
Chloride
expels in the descending limb
Water
which leaves the filtrate by
Passive Transport
through
Aquaporins
inserted in wall of lumen due to
ADH
reabsorbs in the ascending limb
which can contain
