Input stream **cin** in line 8 and 10 will receive the values given by the user and store the same in variable **num1** and **num2.**

Line 11; both the values of **num1** and **num2** will be added and the result will be assigned to the variable **sum**.

(2) char data type:

Character data type accepts and returns all valid ASCII characters. Character data type is often said to be an integer type, since all the characters are represented in memory by their associated **ASCII Codes.** If a variable is declared as char, C++ allows storing either a character or an integer value.

Illustration 9.2: C++ Program to accept any character and display its next character

```
#include <iostream>
using namespace std;
int main()
{
        char ch;
        cout << "\n Enter a character: ";
        cin >> ch;
        ch = ch + 1;
cout << "\n The Next character: " << ch;
}
```

The output produced by the program will be

```
Enter a character: A
The Next character: B
```

In the above program, **ch** is declared as a char type variable to hold a character. When the user enters a character, it will be stored in the **ch** variable as an integer value (ie. Equivalent ASCII code).

ch = ch + 1;

In this statement, the value of **ch** is incremented by 1 and the new value is stored back in the same variable **ch**. (Remember that, arithmetic operations are carried out only on the numbers not with alphabets).
