## 9.16 Type Conversion

The process of converting one fundamental type into another is called as "Type Conversion". C++ provides two types of conversions.

(1) Implicit type conversion

(2) Explicit type conversion.

### (1) Implicit type conversion:

An Implicit type conversion is a conversion performed by the compiler automatically. So, implicit conversion is also called as **"Automatic conversion".**

This type of conversion is applied usually whenever different data types are intermixed in an expression. If the type of the operands differ, the compiler converts one of them to match with the other, using the rule that the "smaller" type is converted to the "wider" type, which is called as **"Type Promotion".**

***For example:***

```
#include <iostream>

using namespace std;

int main()

{

    int a=6;

    float b=3.14;

    cout << a+b;

}
```
