```
void printData(Employee);   // Function declaration
int main()
{
        Employee p;
        cout<< "Enter Full name: ";
        cin>>p.name;
        cout<< "Enter age: ";
        cin>>p.age;
        cout<< "Enter salary: ";
        cin>>p.salary;
        // Function call with structure variable as an argument
printData(p);
return 0;
}
void printData(Employee q)
{
        cout<< "\nDisplaying Information." <<endl;
        cout<< "Name: " << q.name <<endl;
        cout<<"Age: " <<q.age<<endl;
        cout<< "Salary: " <<q.salary;
}
```

**Output:**

```
Enter Full name: Kumar
Enter age: 55
Enter salary: 34233.4
Displaying Information.
Name: Kumar
Age: 55
Salary: 34233.4
```

In the above example, a structure named Employee is declared and used. The values that are entered into the structure are name, age and salary of a Employee are displayed using a function named printData(). The argument for the above function is the structure Employee. The input can be received through a function named readData().
