Note

A member function can access not only the public functions but also the private functions of the class it belongs to.

14.7.1 The Scope Resolution Operator

If there are multiple variables with the same name defined in separate blocks then :: (scope resolution) operator will reveal the hidden file scope(global) variable.

Illustration 14.8 The use of scope resolution operator

```
#include<iostream>
using namespace std;
int a=100;
class A
{
        int a;
        public:
void fun()
        {
        a=20;
        a+=::a;          //using global variable value
        cout<<a;
        } };
int main()
{
        clrscr();
        A a1;
        a1.fun();
        retun 0;
}
```

Recall :: is also used to identify the class to which a member function belongs to.

Output:

120

In the above program the class data member and the global variable have same name. To use the global variable :: used.

14.8 Objects as Function arguments

Objects can also be passed as arguments to a member function just like any other data type of C++.Objects can also be passed in both ways

(1) Pass By Value

(2) Pass By Reference
