www.tntextbooks.in

```
int main()
{
        inner in;
        in.getdata();
        return 0;
}
```

Output:

```
Enter a value10
The given value is 10
Enter a value 20
The given value is 20
```

In the above program class outer and inner are defined separately. But both the classes are connected by the object '*ot*' which is a member of class inner

14.11 Introduction to Constructors

The definition of a class only creates a new user defined data type. The instances of the class type should be instantiated (created and initialized) . Instantiating object is done using constructor.

14.11.1 Need for Constructors

An array or a structure in c++ can be initialized during the time of their declaration.

For example

```
struct sum
  {
        int n1,n2;
  };
class add
  {
        int num1,num2;
  };
int  main()
  {
        int arr[]={1,2,3};        //declaration and initialization of array
        sum s1={1,1};           //declaration and initialization of structure object
        add  a1={0,0};         // class object declaration and initialization throws
                                                          compilation error
   }
```

Member function of a class can access all the members irrespective of their associated access specifier.

The initialization of class type object at the time of declaration similar to a structure or an array is not possible because the class members have their associated access specifiers (private or protected or public). Therefore Classes include special member functions called as *constructors*. The constructor function initializes the class object.
