When you derive the class from an existing base class,it may inherit the properties of the base class based on its visibility mode.So one must give appropriate visibility mode depends up on the need.

Private inheritance should be used when you want the features of the base class to be available to the derived class but not to the classes that are derived from the derived class.

Protected inheritance should be used when features of base class to be available only to the derived class members but not to the outside world.

Public inheritance can be used when features of base class to be available the derived class members and also to the outside world.

16.6 Inheritance and constructors and destructors

When an object of the derived class is created ,the compiler first call the base class constructor and then the constructor of the derived class. This because the derived class is built up on the members of the base class. When the object of a derived class expires first the derived class destructor is invoked followed by the base class destructor.

Illustration 16.7 The order of constructors and destructors

```
#include<iostream>
using namespace std;
class base
{
public:
base()
{
cout<<"\nConstructor of base class...";
}
~base()
{
cout<<"\nDestructor of base class.... ";
}
};
class derived:public base
{
public :
derived()
```
