Notes

The constructors are executed in the order of inherited class i.e., from base constructor to derived. Thedestructors are executed in the reverse order.

Some Facts About the execution of constructor in inheritance

- Base class constructors are executed first ,before the derived class constructors execution
- Derived class can not inherit the base class constructor but it can call the base class constructor by using

  Base_class name::base_class_constructor() in derived class definition
- If there are multiple base classes ,then its start executing from the left most base class
- In multilevel inheritance, the constructors will be executed in the order of inheritance.

Notes

size of derived class object=size of all base class data members + size of all data members in derived class.

16.7 Inheritance and Access Control

When you declare a derived class, a visibility mode can precede each base class in the base list of the derived class. This does not alter the access attributes of the individual members of a base class , but allows the derived class to access the members of a base class with restriction.

As you already know ,you can derive classes using any of the three visibility mode:

- In a public base class, public and protected members of the base class remain public and protected members of the derived class.
- In a protected base class, public and protected members of the base class are protected members of the derived class.
- In a private base class, public and protected members of the base class become private members of the derived class.

In all these cases, **private members of the base class remain private and cannot be used by the derived class**. However it can be indirectly accessed by the derived class using the
