Points to Remember:

- The mechanism of deriving new class from an existing class is called inheritance.
- The main advantage of Inheritance is it supports reusability of code.
- The derived class inherits all the properties of the base class. It is a power packed class, as it can add additional attributes and methods and thus enhance its functionality.
- The various types of Inheritance are Single inheritance, multiple inheritance, hierarchical inheritance and hybrid inheritance
- When a derived class inherits only from one base class, it isknown as single inheritance
- When a derived class inherits from multiple base classes itis known as multiple inheritance
- When a class is derived from a class which is a derived class itself – then this is referred to as multilevel inheritance. The transitive nature of inheritance is reflected by this form of inheritance.
- When more than one derived classes are created from a single base class , it is known as Hierarchical inheritance.
- When there is a combination of more than one type of inheritance, it is known as hybrid inheritance.
- In multiple inheritance, the base classes are constructed in the order in which they appear in the declaration of the derived class.
- A sub-class can derive itself publicly, privately or protectedly.
- The private member of a class cannot be inherited .
- In publicly derived class,the public members of the base class remain public and protected members of base class remain protected in derived class.
- In privately derived class, the public and the protected members of the base class become protected in derived class
- In publicly derived class, the public members of the base class remain public
- and protected members of base class remain protected in derived class.
- When class is derived in protected mode, the public and protected members of base class become protected in derived class.
- constructors and destructors of the base class are not inherited but during the creation of an object for derived class the constructors of base class will automatically invoked.
- The destructors are invoked in reverse order .The destructors of the derived classes are invoked first and then the base class.
- size of derived class object=size of all base class data members + size of all data members in derived class
- overriding of the members are resolved by using :: Scope resolution operator.
- this pointer used to refer the current objects members
