This is because the octet of electron around the sulphur atom is not reached. The reaction is reversible and desulphonation occurs readily in aqueous medium.

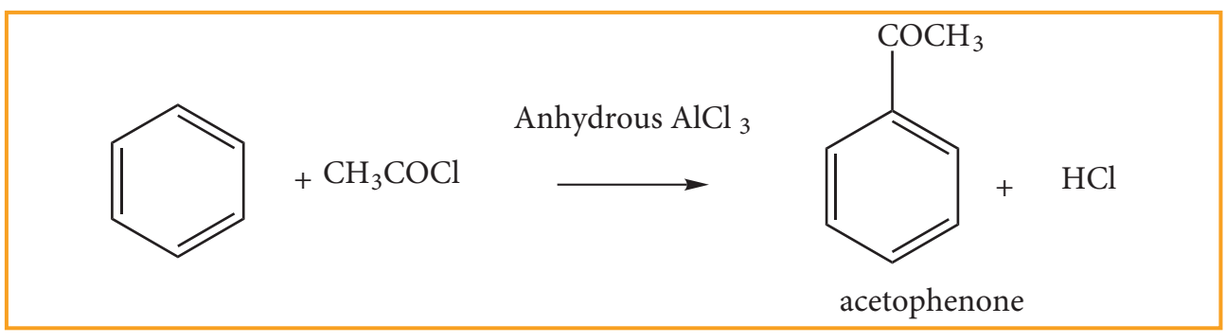

(d) Friedel Craft's Alkylation: (Methylation)

When benzene is treated with an alkyl halide in the presence of only AlCl3, alkyl benzene is formed.

(e) Friedel Craft's Acylation : Acetylation

When benzene is treated with acetyl chloride in the presence of AlCl3, acyl benzene is formed.

(f) Electrophilic Subitution Reactions: Mechanism

Benzene undergoes electrophilic substitution reaction because it is an electron-rich system due to delocalised π electron. So it is easily attacked by electrophilies and gives substituted products.
