Illustration 14.6 Types of constructor

```
#include<iostream>
using namespace std;
class Data
 {
       int i, j;
     public:
       int k;
        Data()
        {
              cout<<"Non Parametrerized constructor";
               i=0;
                j=0;
         }
         Data(int a,int b)
         {
              cout<<"Parametrerized constructor";
               i=a;
                j=b;
         }
        Data(Data &a)
         {
              cout<<"Copy constructor";
               i=a.i;
         }

          void display()            //member function
           {
              cout<< i<<j;
           }
       };
int main()
{
          Data  d1,d2(10,20),d3(d2);
          d1.display();
          d2.display();
          d3.display();
           return 0;

}
```

14.8 Invocation of constructors

There are two ways to create an object using parameterized constructor

- Implicit call
- Explicit call
