Output :

Example: Function with Return Value and with Arguments

The Sum of Passed Values: 65

11.8 Returning from function

Returning from the function is done by using the **return** statement.

The **return** statement stops execution and returns to the calling function. When a **return** statement is executed, the function is terminated immediately at that point.

11.8.1 The return statement

The **return** statement is used to return from a function. It is categorized as a jump statement because it terminates the execution of the function and transfer the control to the called statement. A **return** may or may not have a value associated with it. If return has a value associated with it, that value becomes the return value for the calling statement. Even for void function return statement without parameter can be used to terminate the function.

Syntax:

return expression/variable;

Example : return(a+b); return(a);

return; // to terminate the function

11.8.2 Returning values:

The functions that return no value is declared as void. The data type of a function is treated as **int**, if no data type is explicitly mentioned. For example,

For Example :

int add (int, int);

add (int, int);

In both prototypes, the return value is int, because by default the return value of a function in C++ is of type **int** when no return value is explicitly given. Look at the following examples:

Sl.No	Function Prototype	Return type
1	int sum(int, float)	int
2	float area(float, float)	float
3	char result()	char
4	double fact(int n)	double
