Primary and Secondary Growth

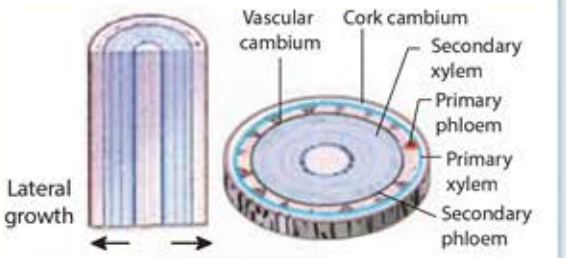

Primary growth in stem

Growth of plant derived from shoot apical meristem increases the length of stem

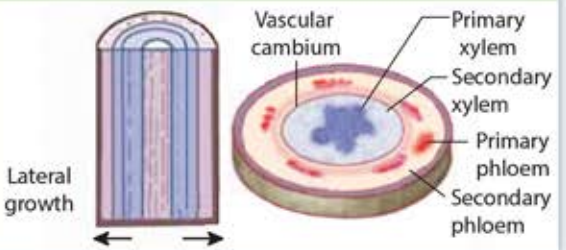

Secondary growth in stem

In gymnosperm and most angiosperm plants, the lateral meristem of stem produces an increase in the girth

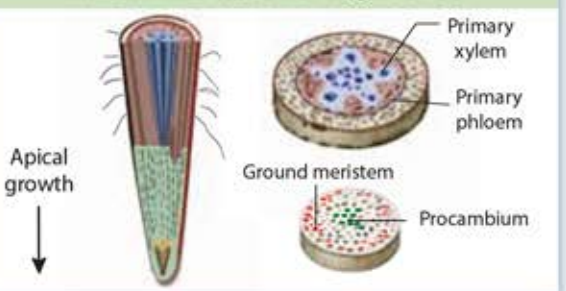

Secondary growth in root

In gymnosperm and most angiosperm plants the lateral meristem of root produces an increase in the girth

Primary growth in root

Growth of plant derived from root apical meristem increases the length of root

APICAL AND LATERAL MERISTEMS.
Apical meristems produce the primary plant body. In some plants, the lateral meristem increase the girth of a plant. This type of growth is secondary because the lateral meristem are not directly produced by apical meristems. Woody plants have two types of lateral meristems: a vascular cambium that produces xylem, phloem tissues and cork cambium that produces the bark of a tree.
